

Philonotis rigida

Rigid Apple-moss

Identification Shoots form dense, brownish-green tufts up to about 1 cm tall, with numerous long rhizoids on the stems. These short stems have longer branches arising from them, with straight, narrow leaves held rigidly erect when moist. The nerve is prominent. Spherical capsules, furrowed when mature, are often produced in spring. The setae are up to 2 cm tall.

Similar species Its congeners lack the rigid habit of *P. rigida*. Young *Bartramia pomiformis* (p. 000) has more strongly toothed leaves, but needs to be checked microscopically.

Habitat A moss of wet cliffs and riverbanks, often in coastal districts, where it may grow on soil and in rock crevices.
